acid sequences of ***ABCG5*** and ***ABCG8*** (C). ***ABCG5*** and ***ABCG8*** are located on chromosome 2p21 between markers D2S177 and D2S 119. (A) ***ABCG5*** and ***ABCG8*** are tandemly arrayed in a head-to-head orientation separated by 374 basepairs. ***ABCG5*** and ***ABCG8*** are both encoded by 13 exons and each spans *28 kb. (B) The mutations detected in patients with sitosterolemia (Table 2) are indicated on a schematic model of ***ABCG5*** (left) and ***ABCG8*** (right) (C) Predicted amino acid sequence of ***ABCG5*** and ***ABCG8***, which are 651 and 673 residues in length, respectively. Alignment of the inferred amino acid sequences indicates 28% sequence identity and 61% sequence similarity between ***ABCG5*** and ***ABCG8***. Both proteins are predicted to contain six transmembrane segments using the program MEMSAT 2 (Jones, et al., Biochem. 33:3038 (1994)). The putative transmembrane segments of each protein are indicated by blue (***ABCG5***) or green (***ABCG8***) cylinders (B) and lines (C). The Walker A motif and Walker B motifs are highlighted in yellow and pink, respectively. The ABC signature sequence (C-motif) is indicated in purple.

FIG. 2. Expression of ***ABCG5*** and ***ABCG8*** in human tissues (A) and the effect of ***cholesterol*** feeding on levels of ***ABCG5*** and ***ABCG8*** mRNAs in mouse liver and intestines (B). (A) Northern blot analysis of human tissues. The coding sequence of ***ABCG5*** and ***ABCG8*** were amplified from liver polyA+RNA (Clontech) and the fragments were cloned into the plasmid vector pGEM-T (Promega). The coding region of the cDNA was amplified and the fragment radiolabeled (Megaprime DNA Labeling System, Amersham) prior to incubation with the blot in Rapid-hyb buffer (1 x 10⁶ cpm/ml) (Amersham). The blot was washed and subjected to autoradiography for 18 h using Kodak X-OMAT-blue film (Jokinen, et al., J. Biol. Chem. 269:26411 (1994)). The results were identical when probes generated from the 3' untranslated regions of both cDNAs were used. (B) ***cholesterol*** feeding induces coordinate increases in levels of ***ABCG5*** and ***ABCG8*** mRNA. Seven-week-old male mice (129S3/SvImj) were fed powdered chow (Harlan Teklad Rodent Diet) in the absence or presence of ***cholesterol*** (2%, w/v). Mice were killed after one or seven days in the light phase of the cycle. Total RNA was isolated using RNA-STAT (TelTest) from the liver and three equal segments of the small intestine (duodenum, jejunum and ileum). The tissue RNAs were pooled from three animals and aliquots (15 µg) used to make duplicate northern blots (Hobbs, et al, Hum. Mutat. 1:445 (1992)). The mouse cDNAs for ***ABCG5*** and ***ABCG8*** were used as probes. Cyclophilin was used as an internal standard. The results were identical when probes generated from the 3' untranslated regions of both cDNAs were used.

FIG. 3. (A) ***ABCG8*** exon 2 (reverse strand) through ***ABCG5*** exon 2 (forward strand). The four exons are underlined and the conserved regions are in uppercase. The sequence ends in intron 2 of ***ABCG5*** and is in the following order: ***ABCG8*** -exon 2 (reverse strand); ***ABCG8*** -intron 1 (reverse strand); ***ABCG8*** -exon 1 (reverse strand); gap between genes; ***ABCG5*** -exon 1 (forward strand); ***ABCG5*** -intron 1 (forward strand); ***ABCG5*** -exon 2 (forward strand); and ***ABCG5*** -intron 2 (forward strand, partial). (B) The sequence between ***ABCG5*** and ***ABCG8*** in which the control sequences (e.g., bidirectional promoter, etc.) reside.

GI 14 Figure(s).

FIG. 1 shows a Northern blot that demonstrates that the LXR agonist Compound (Cpd.) A causes an increase in the level of SSG mRNA in the liver and the intestine.

FIG. 2 shows a Northern blot demonstrating that the LXR agonists Compounds

FIG. 3 shows a Northern blot demonstrating that the LXR agonist Compound A causes an increase in the level of expression of ABC1 in the liver, intestine, and kidney.

FIG. 4 demonstrates that the LXR agonist Compound A stimulates efflux of ***cholesterol*** from Caco-2 cells.

FIG. 5 provides a model for the role of SSG, and the regulation of SSG by LXR-RXR, in cells lining the intestinal lumen. According to this model, SSG plays a role in sterol efflux from the cells lining the intestinal lumen, i.e. SSG plays a role in counteracting the absorption of sterol from the intestine, thus explaining the elevated sterol levels in sitosterolemia patients who lack SSG function.

FIG. 6 provides the structures of the LXR agonists Compounds A, B, and C.

FIG. 7 shows the amino acid and nucleotide sequence for mouse SSG.

FIG. 8 shows the amino acid and nucleotide sequence for human SSG.

FIG. 9 shows a comparison between the mouse and human SSG amino acid sequences.

FIG. 10 shows the results of a mapping experiment for SSG using the Stanford human TNG Radiation Hybrid Panel (Research Genetics), confirming the map position of human SSG of between markers D2S177 and D2S119.

FIG. 11 shows the results of PCR using SSG specific primers and cDNA panels from various tissues.

FIG. 12 shows that human SSG (or human ***ABCG5***) is predominantly expressed in the liver and small intestine.

FIG. 13 shows that mouse SSG (or mouse ***ABCG5***) is predominantly expressed in the liver and small intestine.

FIG. 14 illustrates the cDNA cloning and genomic organization of SSG (or ***ABCG5***) (A). The predicted human and mouse proteins share 80% identity and are 28% identical to Drosophila Brown. Human SSG contains 13 exons and spans at least 25 kb of genomic DNA (B).
